Its diverse range of salmon species are an important part of native cultures and a valuable resource for people in the region. The salmon provide for subsistence, aesthetic, cultural, and economic interests of Alaska Natives, and also provide valuable sport fishing opportunities. Bristol Bay is home to a wide diversity of fish, mammals, birds, and plants. It is important to the health of the region's fish and wildlife, and for Alaska's economic and social well-being. It is part of an important salmon migration route, and provides some of the state's most important ecosystem services. Bristol Bay's biodiversity is represented by more than 5,000 species of plants, birds, and mammals, including 250 species of fish. Because of its location at the junction of three continents, it is one of the most biologically diverse river systems in the world. Salmon in Bristol Bay are the largest run of wild salmon in the world. Nearly half of the world's sockeye salmon and an estimated 70 percent of the world's Pacific salmon runs migrate to the area. Conservation Bristol Bay is an important salmon migration route and host to some of the largest and most valuable salmon runs in the world. 1. Field of the Invention This invention relates to a method for forming a contact hole in an insulating film deposited on a semiconductor substrate, and to a photoresist used for the method. 2. Description of the Prior Art When a large number of MOSFETs and the like are to be formed on one semiconductor substrate, contacts are connected to the source and drain regions of the MOSFETs or to the electrodes of other devices such as resistors or capacitors, and so these contacts must be formed by a highly precise process. When forming these contacts, a photoetching process for etching a part of the surface of the semiconductor substrate is carried out, and a photoresist is used to form a desired contact pattern. With a conventional photoresist, the use of an ultraviolet light, such as a g-line or i-line, is widespread, and a film is formed by depositing a photosensitive material on a surface of a semiconductor substrate by a known process, then a resist pattern is formed by exposure and development, and finally an etching step is carried out using the resist pattern as a mask. However, a resist suitable for the etching of a contact hole for a shallow contact, which is generally used for forming a contact of 1.0.μm or less, is generally formed by a resin, and is therefore generally thick. As a result, when the resist is used as a mask for etching, the etching time can no longer be shortened. Moreover, when the resist is used as a mask for etching, the resist is likely to be damaged during the etching, and consequently when etching is again carried out, the reliability of the contact hole is deteriorated.
